Project Overview

This project analyzes the Maven Fuzzy Factory dataset, which represents an online retailer's website traffic, orders, products and refunds. Working as a team within the Professional Data Analyst Track, we will explore the data end to end: cleaning and validating it, analyzing performance, and presenting insights that support business decisions.

About the Dataset

The dataset is organized as six related tables linked by keys such as order_id, website_session_id, user_id and product_id. Together they cover the full customer journey, from the first website visit through to purchase and any refund.

Table	Description
orders	One row per customer order, with item count, total price and cost of goods sold.
order_items	One row per item within an order, including price, cost and a primary-item flag.
order_item_refunds	Refunds issued against individual order items, with refund amounts.
products	Product catalog with product names and launch dates.
website_sessions	Website visits with traffic source, campaign, device type and repeat-visit flag.
website_pageviews	Individual page views within each session, by URL path.

Project Objectives

- **Prepare the data:** Check data quality, handle missing or inconsistent values and confirm relationships between tables.
- **Analyze sales:** Evaluate revenue, cost of goods sold, margin, order volume and product performance over time.
- **Understand traffic and conversion:** Compare traffic sources, campaigns and device types, and measure how sessions convert into orders.
- **Review refunds:** Examine refund patterns by product and identify where returns affect profitability.
- **Communicate insights:** Present findings with clear visuals and recommendations for the business.
